

Lab 2: ADT Stack Implementations

The goal of this lab is to implement the Stack Abstract Data Type using two different implementations:

- 1) The built in List construct in Python
- 2) The simple linked data structure covered in class

As part of the Stack definition for this lab, we will specify a capacity for the stack. In the case of the Python List implementation, you will allocate a list of size capacity and use this to store the items in the stack. Since Lists in Python expand when more storage is needed, you must avoid using any functions that would cause a List to expand (see the list (haha) of forbidden methods/operations below). This prevents the stack from growing if the user accesses the List through the given interface. (This prevents the stack from using more space than a user might want. Think of this as a requirement for an application on a small device that has very limited storage.) For consistency, in the simple linked data structure implementation, we will also have a capacity attribute for the stack.

You are NOT allowed to use the following Python List operations (we will check!):

- `append()`
- `insert()`
- `extend()`
- `remove()`
- `pop()`
- `del()`
- `+` (concatenations)
- List slicing (except in the `__init__`, `__eq__` and `__rep__` functions provided to you in the starter code for the array implementation)

Additional Requirements:

- All stack operations must have $O(1)$ performance (including the `size()` operation)
- Your stack implementations must be able to hold values of `None` as valid data

The following starter files are available on PolyLearn, and after you have added your code, are the files you will submit for this lab:

- **`stack_array.py`**: Contains an array (Python List) based implementation of the **Stack** class
- **`stack_linked.py`**: Contains a linked based implementation of the **Stack** class
- **`stack_array_tests.py`**: Contains comprehensive tests to ensure your implementations in `stack_array.py` work correctly.
- **`stack_linked_tests.py`**: Contains comprehensive tests to ensure your implementations in `stack_linked.py` work correctly.

(Note that the class in each stack implementation is named **Stack**, and both implementations follow the same specification in regard to the operations on the Stack)
